PAGES LOGIC

1. HEADER

- It will be an HTML file (header.html).
- We shall display our logo in the left top corner in a round circle form (logo will be saved in assets/images/logo.png. Then we shall have the name of the company next then we shall have our bootstrap navigation with buttons Home, Services & Deliveries, Sign Up and Login. We can have Log Out and Admin button as well but initially hidden and only made visible when a user logs in as admin.
- After logging in, we can hide the sign up and login button and then display Log Out.
- We can have the toggle brightness button that toggles between black and white considering the age bracket of the people we're developing for.
- We can use random links for now and we shall link later.
- Our header will have its own CSS named header.css

2. FOOTER

- The first part of our footer will be a section like a progress section that contains some sweet text in the left and then in the right we can have buttons About Us, How to Navigate and Rate Us all these when clicked should open a modal for corresponding messages.
- Then we shall have the quick links, Contact Us for email and phone contact, Location, then follow us with social media platforms
- Our footer will also have its own CSS named footer.css

The logic behind our footer and header will be in the java script file named include.js, we shall use it for including the header and the footer across all pages as well as handling all the logics in both the header and the footer.

3. HOME PAGE

- This will handle the crucial things users need to see and it will be the index page.
- In the hero we shall have a warm message for our viewers and several call-to-action messages
- We shall then display the goal, vision and mission
- We shall display meet our leaders, we shall generate a JSON file with the name, description and image path. We shall display this in a carousel displaying only the pic and the name then description on hovering.
- We then display the company activities in pics and vids stored in uploads folder which has two folders in it images and videos for image and video displays respectively. These can have the button to view details that redirects to the services and delivery page

4. SERVICES & DELIVERIES

- This page displays the activities carried out by the company, so we shall be displaying in category, plans drawn, projects worked on etc. all drawn from the uploads folder but in categories. These will be uploaded by the admin.

5. SIGN UP PAGE

- This captures information about the user like first name, second name, address, contact, gender, then we select the role or category according to what the company

offers. Like one can register as a client, applicant, etc but for now we shall allow only clients, if the user selects anything else, we can inform them it's not supported now and grey them out but still give feedback on hovering or clicking, then we submit. We shall use jQuery to hide the submit button till all fields are filled.

6. LOGIN PAGE

- This captures the user's credentials (username and password), then does the authentication, then sets the session storing every information we shall be needing throughout. Check role, if its admin, redirect to admin dashboard, if client , then redirect to client's page, we shall display a welcome message to them basing on the day time , then their second name, like Good morning , welcome user_name.

NB: We shall have separate html, js and php files and css just in case for sign up and login pages.

7. THE ADMIN DASHBOARD

- This is where we got a lot to do. We shall have a sidebar that can be toggled to hide or unhide so that we can have a wide field of view and then the main content area where we shall be viewing from
- By default, our main content will be displaying statistics from the database about the system, like clients worked on and other things that deem necessary
- Our side bar will have parent buttons that when clicked collapses with the child buttons that when clicked will fetch the pages via AJAX to the main content area

ACTIVITIES

- **Members management.** Here we can **register** new clients (can just utilize the sign up page), then **view** clients. In the viewing, we can use that bootstrap technique of performing the delete and the update just on viewing, so can just have those icons there as well**.** we can even use this to edit the user role as well even if we didn't enter it at first.
  Then we can **assign login credentials** to the clients. Can implement a search for client by name, then assign them their credentials.
- **Item Management.** Here we can **register item category** first, then afterwards for each item we shall be registering, we select category first, then register the item and the unit price.
  - We also implement the **view items** and still should be able to delete and edit item prices since they can fluctuate, we can also filter by category or name
- **DESIGN QUOTATION.** This is a key area, it's the heart of the system. My plan is like we select the client, then we can fetch items by category from the database, then enter the quantity, then we perform the calculation to get the total per item and the overall. We should account for edits as well as u know things of budget.
  Then we also implement the **view** that will display the quotation in a table very well. We can implement printing as PDF, ensure it has the logo on top and etc.

- **Uploads.** The admin will be uploading all the files both images and videos for their activities. So he can register category like construction, plan drawing etc.

we save these in respective folders created automatically, then can provide a description of the upload for example if its construction, can give the description and location of the site etc,,I don't know how we can enable editing and deleting in this but we need it.

These uploads will be the one displayed in the Services & Delivery page. Create fields for the category and populate everything under that category.

- Implement a notification for the admin just in case of any sign up or anything necessary

8. **CLIENT PORTAL.** This is the client view area specifically for their invoices. we should keep in mind that the client can have more than one invoice, maybe the first budget may have been revised, so the client can view all those and then can print PDF, with the company logo on top then company name.

NOTE:

I. Considering our users, most of them will be using the system but with their phones, so let's ensure good appearance and responsiveness on mobiles. It will be a web app but lets be as if we're doing a mobile app. We can borrow from an app called Live score that shows football fixtures and etc, so lets make it hard to even realize it's a web app.

II. Let's employ color that suits our age bracket (35 years) and above so that even when we toggle, visibility keeps on

III. Make good use of icons since most of the users are not tech-savvy

IV. Use a lot of icons and lets ensure system is easy to use.

V. Make the system sooooo nice please and attractive, make it inject good feelings in the user, lets design for good UX ensuring all pinciples of HCI and Usability are applied

VI. We can use voice where necessary for the users that have hardship in reading
